WHITEPAPER V0.8 · 23 AUGUST 2026

GumBall6900

The index fund that chooses itself

An immutable signal-directed onchain fund with continuously clearing GBX mining, tenure-locked miner rates, oracleless acquisitions, and in-kind redemption.

0	**16**	**80 / 20**	**Fixed**
PREMINTED GBX	MINING SLOTS	HANDOFF / RESONANCE	TENURE RATE

READ THIS FIRST

Development design, not a deployed system.

GumBall6900 is experimental software. It is not deployed, has not received an independent external audit, and is not authorized for user funds. Independent review of Mine's fixed economics, target-chain dependencies, legal provenance, and a signed deployment manifest remain unresolved.

This edition describes the uncommitted development tree implementing ADRs 0031, 0033-0047, 0049, and 0050. There is no commit-pinned review candidate. External governance remains unselected. A local green build is engineering evidence, never a safety, audit, or release claim.

EDITION

v0.8, 23 August 2026. Not deployed and not authorized for user funds. Independent external audit not completed.

Initial supply	Zero; GBX creates no tokens at deployment
Lifetime issuer	One permanently bound immutable Mine
Supply limit	No economic cap; GBX has no voting checkpoints
Governance	External Resonance owner unselected; sGBX IVotes retained
Legal status	donut-miner, give.fun, Liquid Signal, and transitive lineage remain unresolved release blockers

ORIENTATION

Contents

PART I

01 The economic loop

Mining brings USDG in; signal-backed sGBX coordinates acquisition weights and exposes IVotes checkpoints.

01 A participant takes a mining slot at its current hourly decaying USDG price.

02 The incumbent accrues GBX continuously at the fixed rate assigned on entry.

03 A signal atomically escrows GBX, mints non-transferable voting sGBX, and assigns every unit to one live Strategy.

04 Twenty percent of a nonempty-slot handoff is deposited into ResonanceRouter; eighty percent becomes a displaced-miner claim.

05 Mine stops after deposit. A later permissionless route of a qualifying balance restarts seven days with new USDG plus the remainder.

06 Strategies pull released USDG; each acquired-asset payment uses the current global 0%-to-20% Bribe rate and its Fund complement, with 1e36 reward-index precision.

07 A reviewed external USDG-GBX LP token may be a bootstrap Strategy asset; it receives no special core treatment.

08 A GBX holder may burn GBX for a selected pro-rata basket of raw Fund assets.

EMPTY SLOTS

A first occupation deposits 100% into the Router. Mine stops there; permissionless routing has no guaranteed caller.

NO TEAM FEE

Mining has no team, founder, management, or protocol fee.

PART II

02 A continuously clearing market

Each independently replaceable slot falls from its opening USDG price to zero in one hour.

A miner buys the right to accrue GBX until replacement and the possibility of receiving 80% of the next payment. The second value is uncertain: without a successor, no handoff claim arrives. This rollover risk disciplines the price miners are willing to pay.

After each handoff, the next opening price is the paid amount multiplied by an immutable factor, with an immutable minimum. Expected GBX value, market liquidity, gas, replacement probability, and contract risk all influence the real clearing price.

MOMENT	CONTRACT OUTCOME
Start of hour	Price equals the slot opening price
Thirty minutes	Approximately half remains
One hour or later	Price is zero; replacement still allowed
Nonempty replacement	80% claim / 20% Router deposit

NOT GUARANTEED

Profitability, a successor payment, GBX liquidity, and frequent replacement are market outcomes—not contract guarantees.

CALLER BOUNDS

Every purchase supplies an expected epoch, a deadline, and a maximum price, so a miner front-run at purchase cannot be charged the reset opening price.

PART III

03 Miners keep the rate they bought

A slot rate changes only when that slot changes hands.

Time-based halving boundaries, claims, redemptions, and other slots' handoffs never rewrite an occupied slot's GBX-per-second rate.

STATE	EARLIER INCUMBENT	NEW TENURE
Global 230,400 GBX/hour	14,400 GBX/hour	14,400 GBX/hour
Global rate halves	Still 14,400 GBX/hour	7,200 GBX/hour
Incumbent is replaced	Tenure ends	7,200 GBX/hour

All sixteen slots divide the current global rate by sixteen when a tenure begins. A time boundary changes only the rate offered at a later handoff, never an incumbent's already-assigned rate.

ACCEPTED TRADEOFF

Aggregate issuance can exceed the current global rate for as long as old high-rate tenures remain; turnover is not guaranteed.

PART IV

04 Accrued mining counts before redemption

Fund reads Mine's constant-time effective supply before taking the common snapshot.

GBX begins with NaN genesis tokens. Its only later issuer is the permanently bound Mine. Global rates offered to future occupants halve every 69 days measured from Mine deployment and reach a 1 GBX-per-second tail at day 414. That schedule is provisional pending independent economic review. GBX supports permit approvals but has no governance checkpoints; votes begin only after signaling into sGBX.

Rewards accrue continuously but each slot mints only when it changes hands. Fund reads Mine's constant-time effective supply before every redemption, so already-earned unminted GBX cannot be omitted from the denominator and redemption never depends on touching all slots.

>
> ```
> floor(Fund token balance × GBX burned ÷ effective
> pre-burn supply)
> ```

CONSTANT-TIME SUPPLY

Mine maintains one aggregate TPS accumulator across 16 fixed slots; Fund performs no slot loop or mining mutation.

OMISSIONS

Assets a redeemer leaves out remain permanently for the post-redemption supply.

PART V

05 Immutable by design

The core exposes four Resonance administration methods; external execution rules remain unselected.

RESONANCE OWNER ACTIONS

- Add a Strategy
- Permanently kill a Strategy
- Register a Bribe reward token, up to sixteen
- Set the global prospective Bribe share, 0%-20%

ABSENT POWERS

- No Mine administration or incumbent repricing
- No emission setter or replacement authority
- No core Governor, Timelock, or generic executor
- No Fund withdrawal or liquidity-specific core custody

SignalGBX retains block-clock ERC20Votes checkpoints, including historical weight after signal exits, but this repository does not select or implement the governance system that will consume them. A later ADR must pin the exact external executor, permissions, voting rules, upgrades, delay, cancellation, and ownership handoff. After bootstrap, the final live Strategy cannot be killed until a replacement is added. A rate change affects only later payment classifications; 0% disables no signaling or independently funded reward path.

RELEASE STATUS

External governance selection, independent audit, parameter review, provenance clearance, and signed deployment evidence are still required.
