

GumBall6900

The index fund
that chooses itself

An immutable signal-directed onchain fund with continuously clearing GBX mining, tenure-locked miner rates, oracleless acquisitions, and in-kind redemption.

READ THIS FIRST

Development design, not a deployed system.

GumBall6900 is experimental software. It is not deployed or authorized for user funds. V12 supplied a finding export for the exact source target, but the package is incomplete. Independent disposition confirmed three historical behaviors. ADR 0053's claim-authorization remediation was internally verified before ADR 0054 added the Mine genesis issuance and atomic launcher, which also removes the canonical graph's prior multi-transaction pre-handoff exposure window. ADR 0055 then added Mine's validated future-revenue Router migration and two-step Mine and Resonance handoffs. Fresh independent closure remains open. Mine economics, target-chain dependencies, legal provenance, and a signed deployment manifest remain unresolved.

This edition describes the uncommitted development tree based on f991253 and reconciled through ADR 0055; V12 remains pinned to 3ae171b. External governance remains unselected. Internal verification and the received export are bounded evidence, never a safety or release claim.

EDITION

v0.11, 30 August 2026. Not deployed and not authorized for user funds. V12 export received; complete assurance and release closure pending.

GBX constructor supply	Zero; the temporary setup minter cannot mint
Canonical launch supply	1,000 GBX, issued by Mine only into permanently locked genesis liquidity
Lifetime issuer	One permanently bound immutable Mine
Supply limit	No economic cap; GBX has no voting checkpoints
Governance	External Resonance owner unselected; sGBX IVotes retained
Legal status	donut-miner, give.fun, Liquid Signal, and transitive lineage remain unresolved release blockers

03	Fixed-tenure fairness	06			

PART I

01 The economic loop

Mining brings USDG in; signal-backed sGBX coordinates acquisition weights and exposes IVotes checkpoints.

- 01 A participant takes a mining slot at its current hourly decaying USDG price.
- 02 The outgoing tenure accrues GBX continuously at the fixed rate assigned on entry.
- 03 A signal atomically escrows GBX, mints non-transferable voting sGBX, and assigns every unit to one live Strategy.
- 04 Twenty percent of a nonempty-slot replacement is deposited into ResonanceRouter; eighty percent becomes an outgoing-tenure miner claim.
- 05 Mine stops after deposit. A later permissionless route of a qualifying balance restarts seven days with new USDG plus the remainder.
- 06 Strategies pull released USDG; each acquired-asset payment uses the current global 0%-to-20% Bribe rate and its Fund complement, with 1e36 reward-index precision.
- 07 Before market use, the one-shot launcher seeds 1 USDG plus 1,000 Mine-issued GBX into the canonical V2 pair and locks every genesis LP unit at zero.
- 08 GBX and the actual LP token are the two initial Strategies; later Fund-held LP remains ordinary caller-selectable redemption backing.
- 09 A GBX holder may burn GBX for a selected pro-rata basket of raw Fund assets.

EMPTY SLOTS

A first occupation deposits 100% into the Router. Mine stops there; permissionless routing has no guaranteed caller.

NO TEAM FEE

Mining has no team, founder, management, or protocol fee.

PART II

02 A continuously clearing market

Each independently replaceable slot falls from its opening USDG price to zero in one hour.

A miner buys the right to accrue GBX until replacement and the possibility of receiving 80% of the next payment. The second value is uncertain: unless a later replacement clears at a nonzero price, no outgoing-tenure claim arises. Because self-replacement is permitted, this rollover risk is about the clearing price rather than a required change of miner.

After each replacement, the next opening price is the paid amount multiplied by an immutable factor, with an immutable minimum. Expected GBX value, market liquidity, gas, replacement probability, and contract risk all influence the real clearing price.

NOT GUARANTEED

Profitability, a nonzero later replacement payment, GBX liquidity, and frequent replacement are market outcomes—not contract guarantees.

CALLER BOUNDS

Every purchase supplies an expected epoch, a deadline, and a maximum price, so a miner front-run at purchase cannot be charged the reset opening price.

MOMENT	CONTRACT OUTCOME
Start of hour	Price equals the slot opening price
Thirty minutes	Approximately half remains
One hour or later	Price is zero; replacement still allowed
Nonempty replacement	80% claim / 20% Router deposit

PART III

03 Miners keep the rate they bought

A slot rate changes only when its next tenure begins.

Time-based halving boundaries, claims, redemptions, and other slots' replacements never rewrite an occupied slot's GBX-per-second rate.

STATE	OUTGOING TENURE	NEW TENURE
Global 230,400 GBX/hour	14,400 GBX/hour	14,400 GBX/hour
Global rate halves	Still 14,400 GBX/hour	7,200 GBX/hour
Replacement clears	Outgoing tenure ends	7,200 GBX/hour

All sixteen slots divide the current global rate by sixteen when a tenure begins. A time boundary changes only the rate offered at a later replacement, never an outgoing tenure's already-assigned rate.

ACCEPTED TRADEOFF

Aggregate issuance can exceed the current global rate for as long as old high-rate tenures remain; turnover is not guaranteed.

PART IV

04 Accrued mining counts before redemption

Fund reads Mine's constant-time effective supply before taking the common snapshot.

GBX's constructor begins with 0 tokens. After the permanent Mine binding, the canonical launcher directs Mine's fixed 1,000 GBX issuance only into the 1 USDG genesis pair and permanently locks the resulting LP. There is no team, presale, treasury, or discretionary allocation. Global rates offered to future occupants halve every 69 days measured from Mine deployment and reach a 1 GBX-per-second tail at day 414. That schedule is provisional pending independent economic review. GBX supports permit approvals but has no governance checkpoints; votes begin only after signaling into sGBX.

Mining emission accrues continuously but each slot mints only when its current tenure is replaced. Fund reads Mine's constant-time effective supply before every redemption, so already-earned unminted GBX cannot be omitted from the denominator and redemption never depends on touching all slots.

PAYOUT

$$\text{floor}(\text{Fund token balance} \times \text{GBX burned} \div \text{effective pre-burn supply})$$

CONSTANT-TIME SUPPLY

Mine maintains one aggregate TPS accumulator across 16 fixed slots; Fund performs no slot loop or mining mutation.

OMISSIONS

Assets a redeemer leaves out remain permanently for the post-redemption supply.

PART V

05 Immutable by design

Five bounded actions span Mine and Resonance; external execution rules remain unselected.

CONTINUING OWNER ACTIONS

- Set Mine's validated future-revenue Router
- Add a Strategy
- Permanently kill a Strategy
- Register a Bribe reward token, up to sixteen
- Set the global prospective Bribe share, 0%-20%

ABSENT POWERS

- No Mine slot, price, emission, or outgoing-tenure repricing
- No emission setter or replacement authority
- No core Governor, Timelock, or generic executor
- No Fund withdrawal or continuing liquidity manager

SignalGBX retains block-clock ERC20Votes checkpoints, including historical weight after signal exits, but this repository does not select or implement the governance system that will consume them. A later ADR must pin the exact external executor, permissions, voting rules, upgrades, delay, cancellation, and ownership handoff. After bootstrap, the final live Strategy cannot be killed until a replacement is added. A rate change affects only later payment classifications; 0% disables no signaling or independently funded reward path.

RELEASE STATUS

Finding treatment, complete external assurance, governance selection, parameter review, provenance clearance, and signed deployment evidence are still required.
